Abstract

As nature's wonderful gift, several hot water springs occur in Sri Lanka though it does not fall within very active tectonic zone in the earth. They are mostly confined to the eastern sector of the island. However, hot water springs at Mahapelassa off Embilipitiya, Kanniyai off Trincomalee and Mahaoya are well known to people. These thermal springs show their out flow temperature ranging between 34°C to 56°C . The hottest springs lie at Kapurella (56°C), followed by Mahaoya (55°C), Marangala-Wahawa close to Padiyatalawa ($42-45^{\circ}\text{C}$), Mahapelassa ($44-46^{\circ}\text{C}$) and Nelumwewa, which was known earlier as Madawewa and now under a lake, records 45°C in mud samples (Fonseka 1994). The present research was aimed out mainly to model the formation of hot water springs in Sri Lanka based on geological and tectonic settings using geological, geophysical and Remote Sensing techniques while evaluating the hot water springs for their potential as energy resources or development as places for eco-tourism.

Geological, structural and tectonic setting of the areas have been studied using geological, geochemical and geophysical techniques. Both field and laboratory studies were carried out in order to compile geological and geophysical profiles and to determine geochemical and physical parameters of hot water springs in Sri Lanka.

According to the results of this study, the major boundary between Highland Complex and Vijayan Complex show multiple thrust planes and shear zones showing imbricated lithological slices of both Highland Complex and Vijayan Complex. Other than the ductile structures, brittle fractures, joints and fault planes extend as mega lineament for several kilometers. These lineaments produce good secondary aquifer conditions with adequate porosity. The surface mapping and geophysical evidence of the lineaments show that they are very deep and are interconnected. Therefore, they offer better pathways for surface water to percolate deep levels and return upwards with adequate pressure to reach the surface after heating. These structurally controlled hot water springs in Sri Lanka are associated with deep geologically weak zones of fracture or fault systems within the tectonically active thrust boundary.

According to geochemical parameters and field evidence, hot water springs in Sri Lanka can be divided into three groups, Group 1: Mahapelassa Group 2: Kapurella, Mahaoya, Padiyatalwa, Palanoya and other around the Mahiyangana, Ampara and Group 3: Kannai, Rathkhiriya and Adampane areas.). According to the chemical and physical parameters of hot water it can be concluded that Group (1) and Group (3) are more suitable for therapeutic uses and have a good potential for development for eco-tourism. The Group (2) has hot water with low contaminations of salt, and show fairly high potential for generation of geothermal energy.

ACKNOWLEDGEMENTS

At the outset I would like to record with deep respect and gratitude for the valuable guidance and encouragements given by my Supervisors, Professor Dayantha Wijesekara (Former Vice-Chancellor, University of Moratuwa), Mr. S. Weerawarnakula, Dr. U.G.A. Puswewala and Dr. A.M.K.B. Abeysinghe. The support and the most willing assistance extended by Dr. Kithsisri Dissanayake (Former Head / Department of Earth Resources Engineering), Professor W.D.W. Jayathilake (Department of Chemistry, University of Sri Jayewardenepura) and Professor Ananada Gunathilake are acknowledged with utmost gratitude.

Dr. Nanada Munasinghe, Director Postgraduate Studies is acknowledged greatly for his kind cooperation and assistance. I would also like to express my sincere gratitude to all members of Academic and Technical staff of the Department of Earth Resources Engineering for their kind assistance and support extended to me during the research.

A special thanks for Mr. G. Kumasaru for giving the fullest cooperation during the field work. I am also thankful to villagers around Padiyatalawa for their kind assistance given to me during field work. Mr. G. Jayasena (Custom Department) would be remembered with most gratitude for his kind support during the field works.

The members of the staff of Environmental Engineering Laboratory, Department of Civil Engineering, University of Moratuwa and Shamalee Siriwardane (Chief Chemist, Geological Survey and Mines Bureau) are also greatly acknowledged for their invaluable support for chemical analysis. All the geologists at Geological Survey and Mines Bureau are also thanked for their kind assistance.

Special thanks are due to the Senate Research Committee for awarding me a university research grant for this study. The valuable guidance, unreserved support offered by many others are remembered with profound gratitude. I regret the inability to mention all of them by name.

TABLE OF CONTENTS

Abstract	i
